# What are the Invisibles?

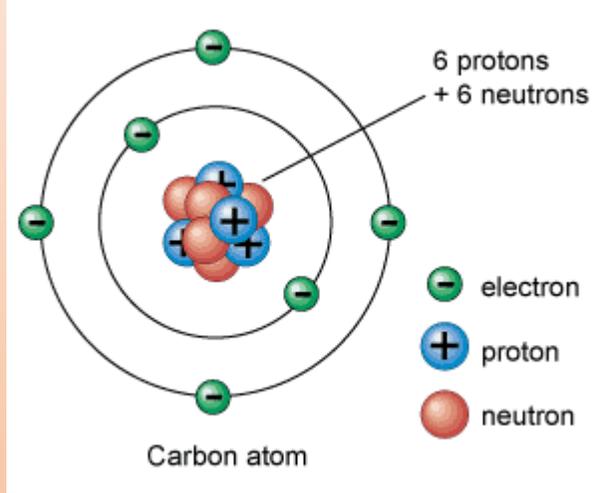

in**o**visibles

neutrinos, dark matter & dark energy physics

# What we know.

## At the macroscopic level...

Matter

....

# Four fundamental forces:

-Gravity

-Electromagnetic

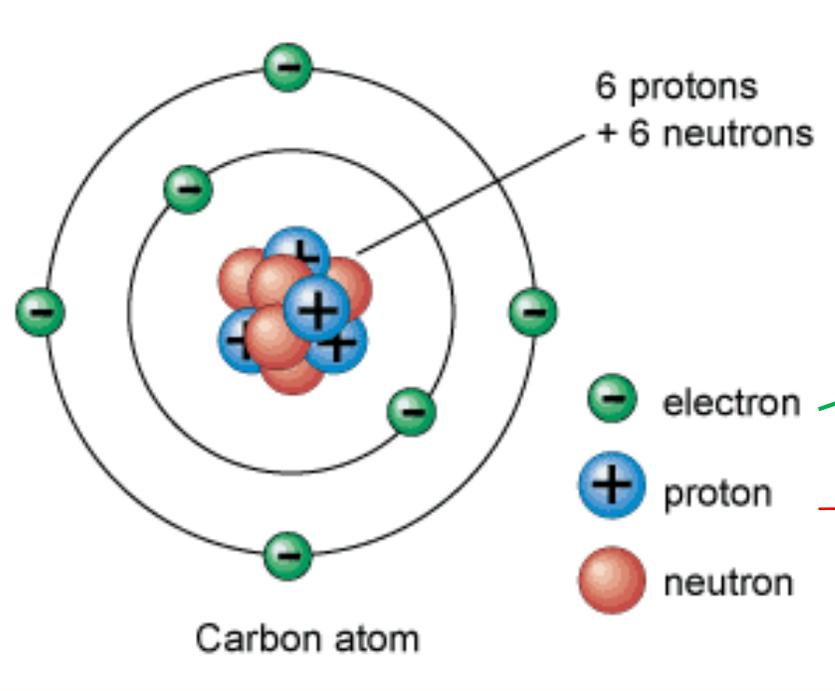

-Strong Interaction

-Weak Interaction

Nuclear forces

A diagram consisting of two green arrows pointing from the text 'Strong Interaction' and 'Weak Interaction' towards the text 'Nuclear forces'. The arrows originate from the right side of the 'Strong Interaction' and 'Weak Interaction' text and converge towards the 'Nuclear forces' text.

# At the **fundamental** level

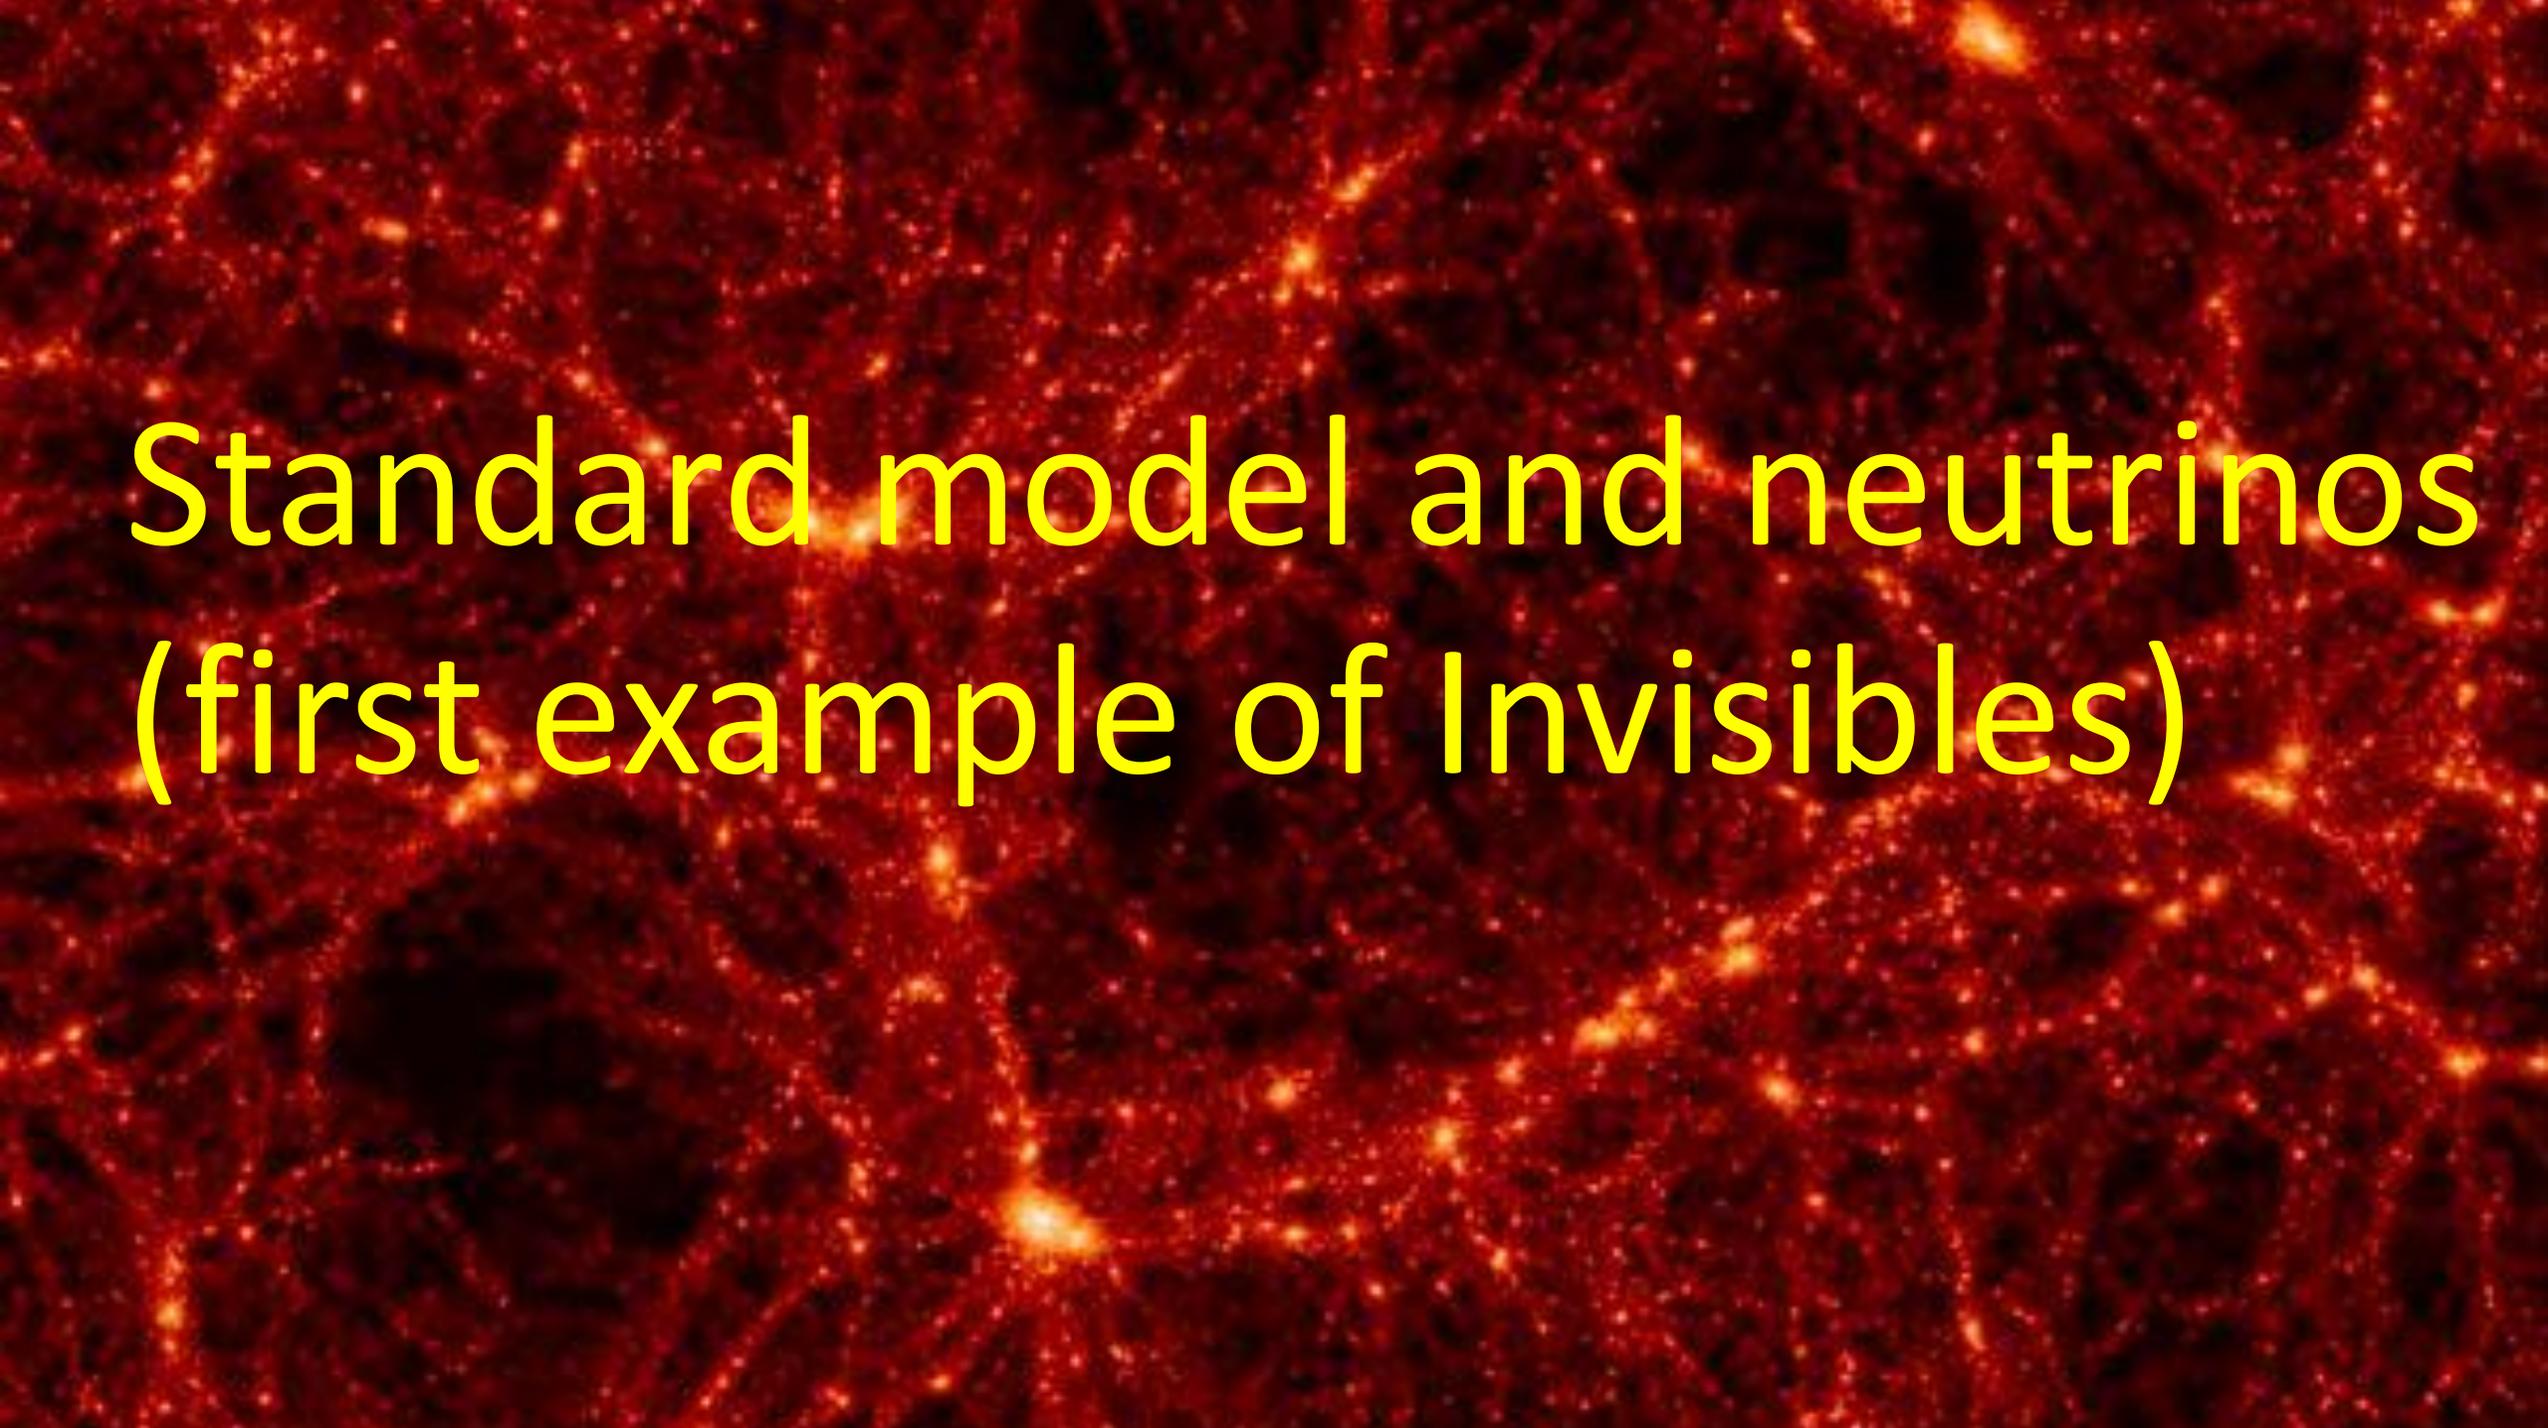

Elementary particle

Not elementary particles.  
Constituted by elementary particles: **quarks**

Electromagnetic, strong and weak interactions are described at the fundamental level by the **Standard Model of Particle Physics (SM)**.

Gravity evades a unified picture. Only macroscopic description provided by Einstein's relativity.

# Standard model and neutrinos (first example of Invisibles)

# Quarks

u up	c charm	t top
d down	s strange	b bottom

# Leptons

e electron	$\mu$ muon	$\tau$ tau
$\nu_e$ electron neutrino	$\nu_\mu$ muon neutrino	$\nu_\tau$ tau neutrino

# Force Carriers

Z Z boson	$\gamma$ photon
W W boson	g gluon

H  
Higgs boson

Electromagnetic interaction

Weak interaction

Strong interaction

Neutrinos are almost massless particles with a very tiny probability of interaction with the other particles.

Whatever material is substantially transparent to neutrinos. They are apparently undetectable.

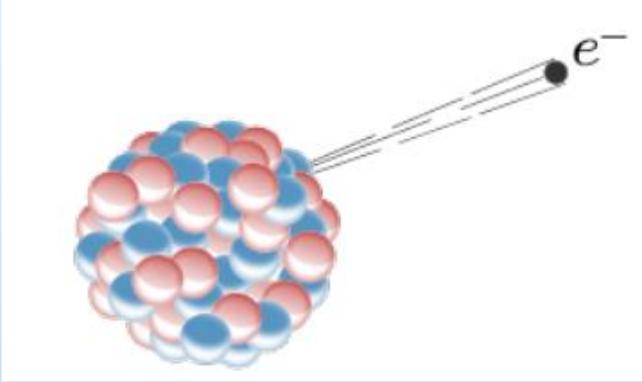

They are (almost) invisibles.

How one can detect an (almost) invisible particle?

# Option 1:

Even undetectable particles can indirectly affect observable phenomena.

## Example: Beta-decay

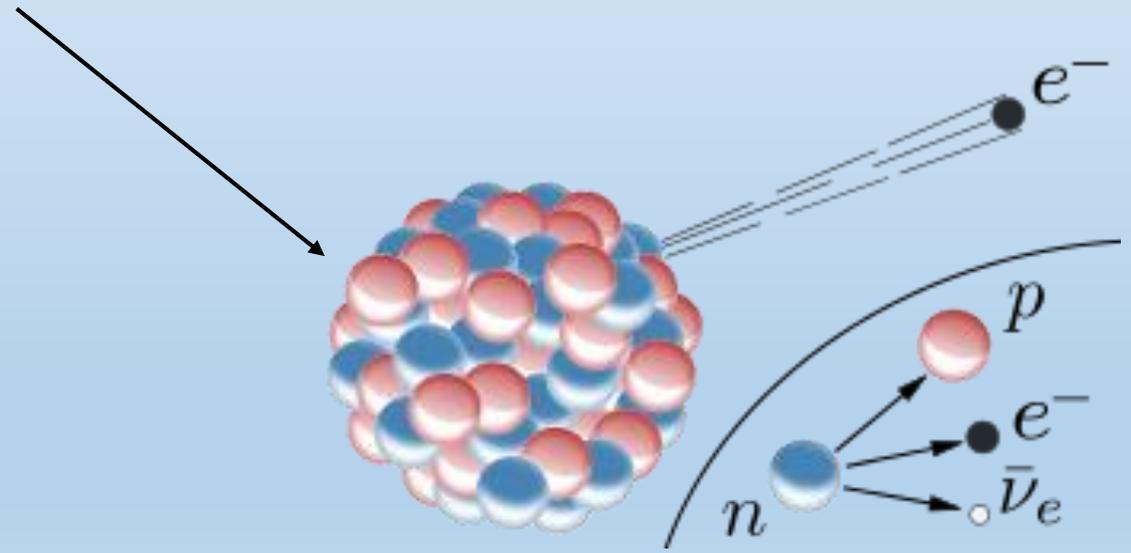

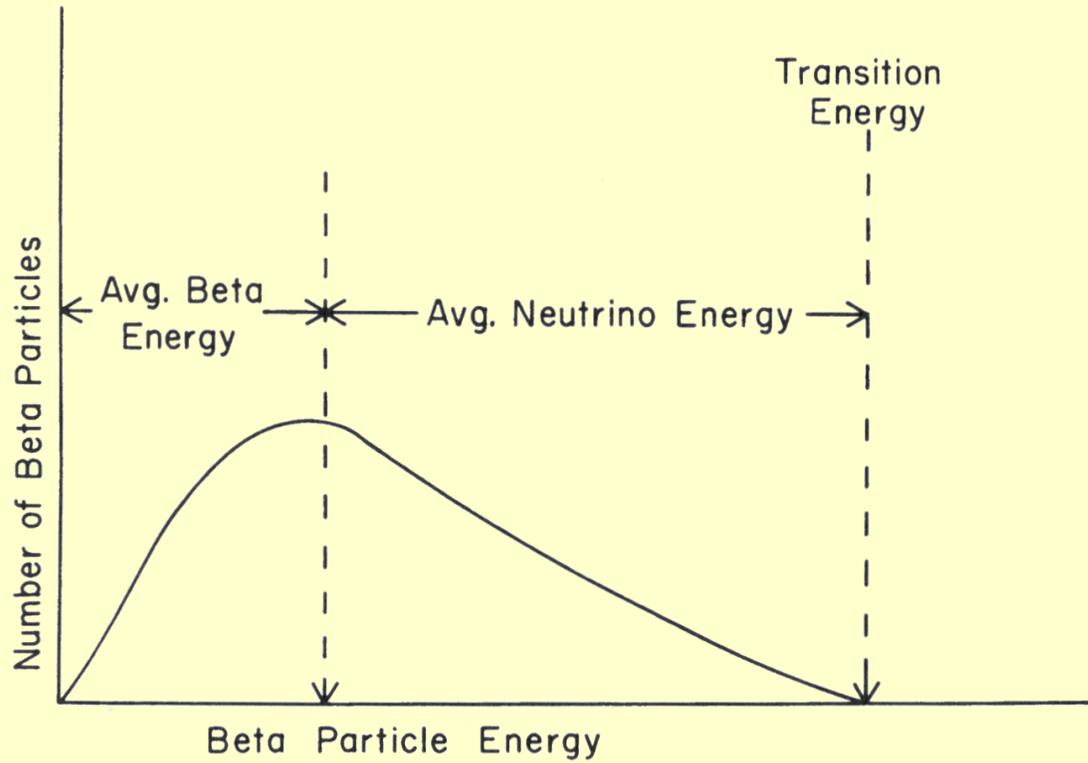

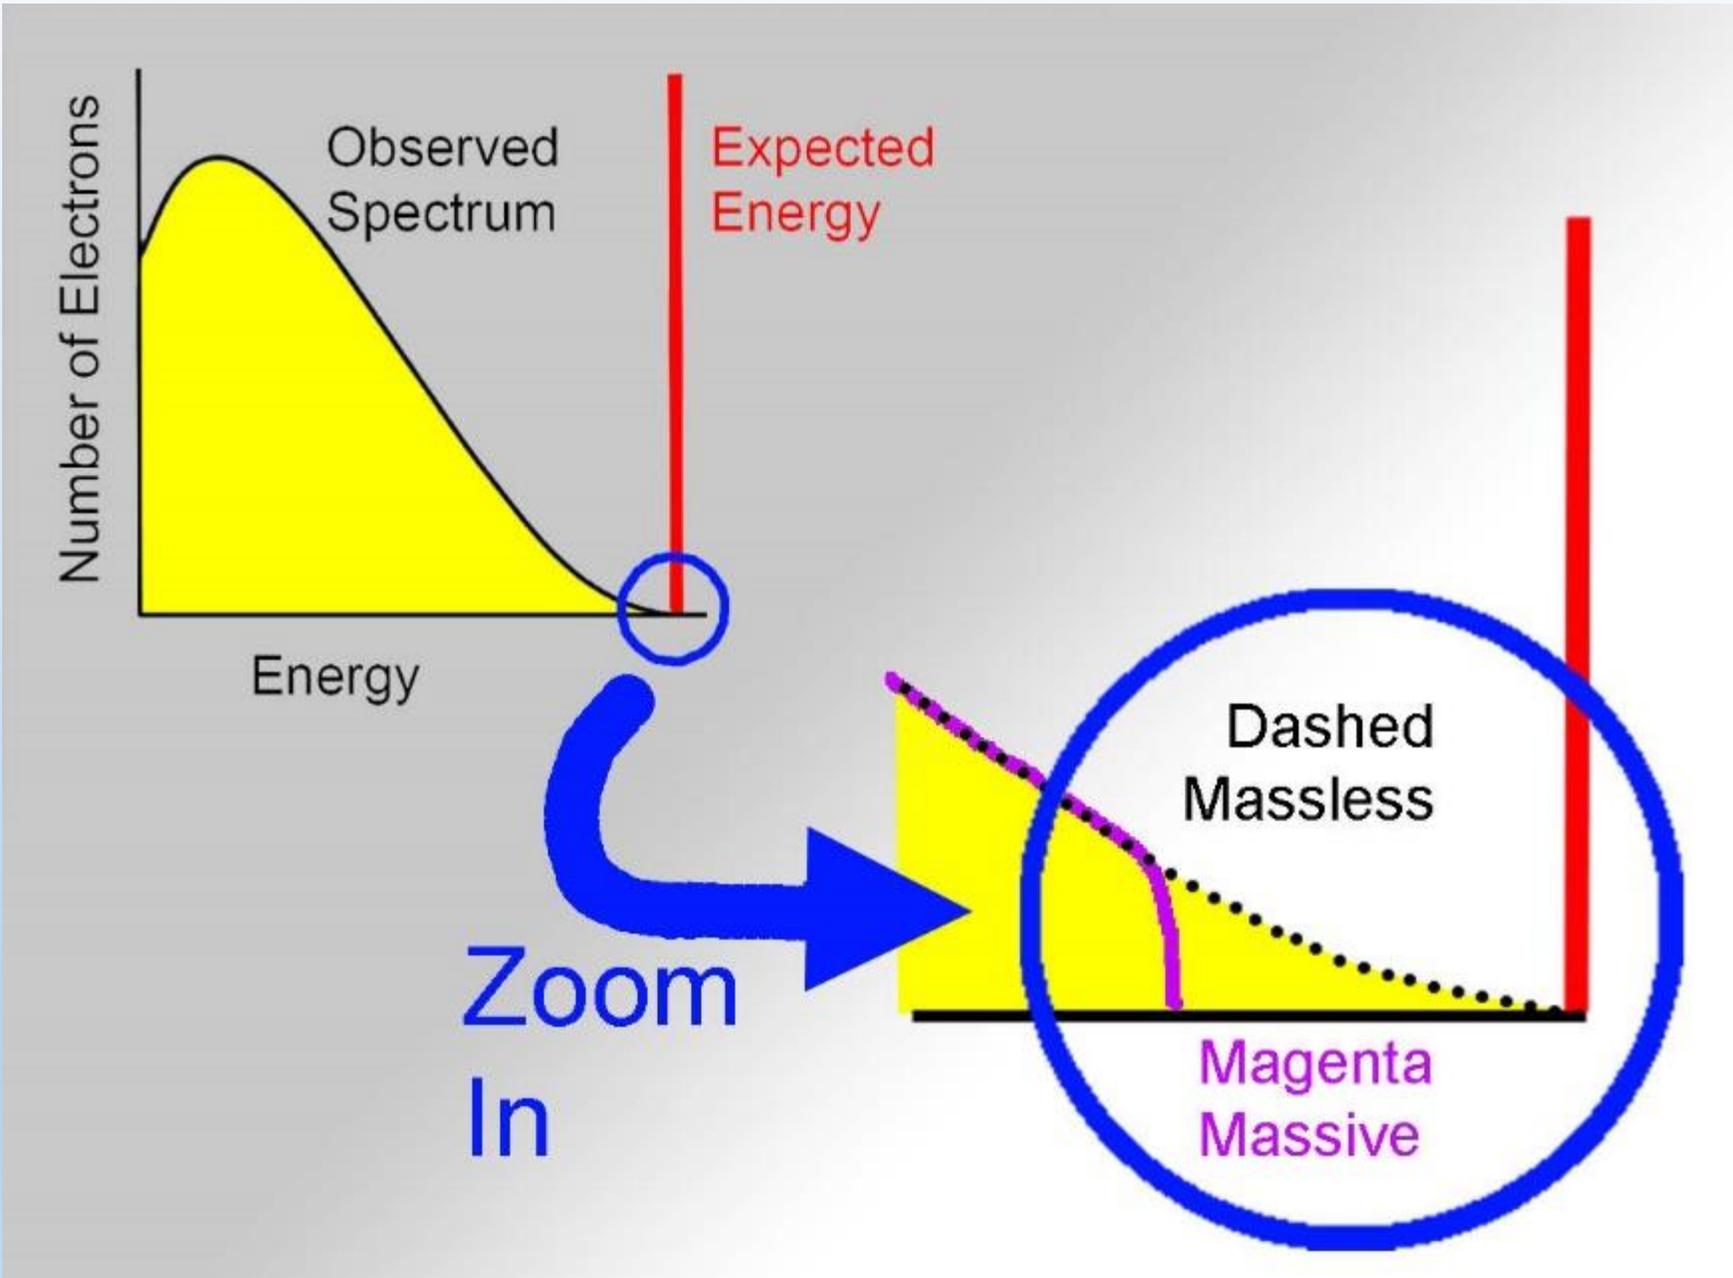

Beta-decay: decay of a nucleus with the emission of electrons.

In a world without neutrinos energy conservation would imply fixed energy for the emitted electrons, approximately given by the mass difference between the original and the daughter nucleus.

However...

The energy of the electrons is not fixed. This is possible only if there is another (invisible) decay product.

## Option 2:

Low probability of detection can be compensated by a very efficient source

*(Phys.Rev.Lett. 9, 36, 1962)*

**OBSERVATION OF HIGH-ENERGY NEUTRINO REACTIONS AND THE EXISTENCE  
OF TWO KINDS OF NEUTRINOS\***

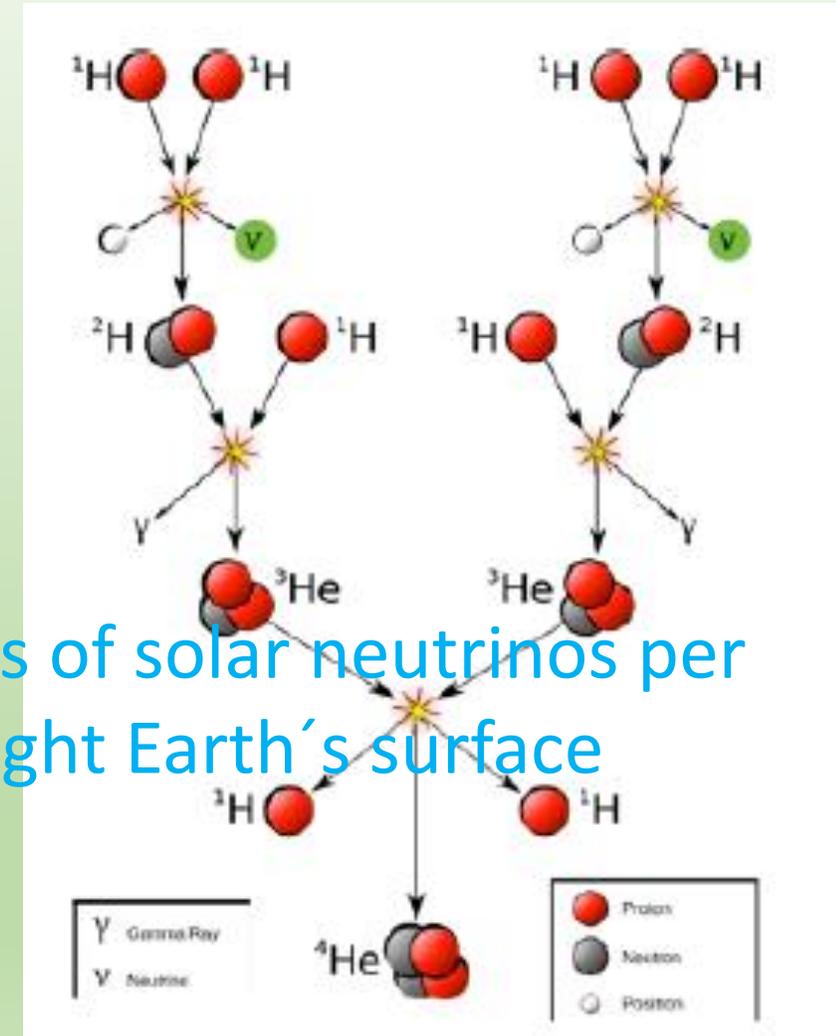

Very efficient source of neutrinos

# The sun is an extremely powerful source of neutrinos

Hundred of billions of solar neutrinos per second pass through Earth's surface

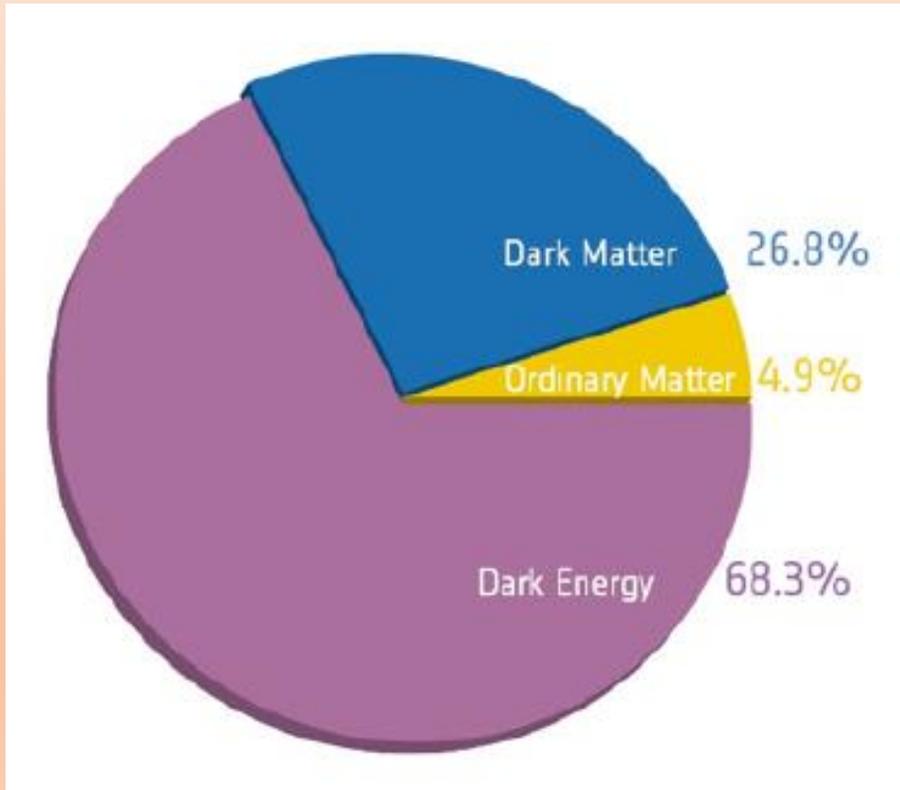

# Beyond the Standard Model: Dark Matter

The Standard Model provides a successful description of observed phenomena.

However the majority of the Universe is “Invisible”

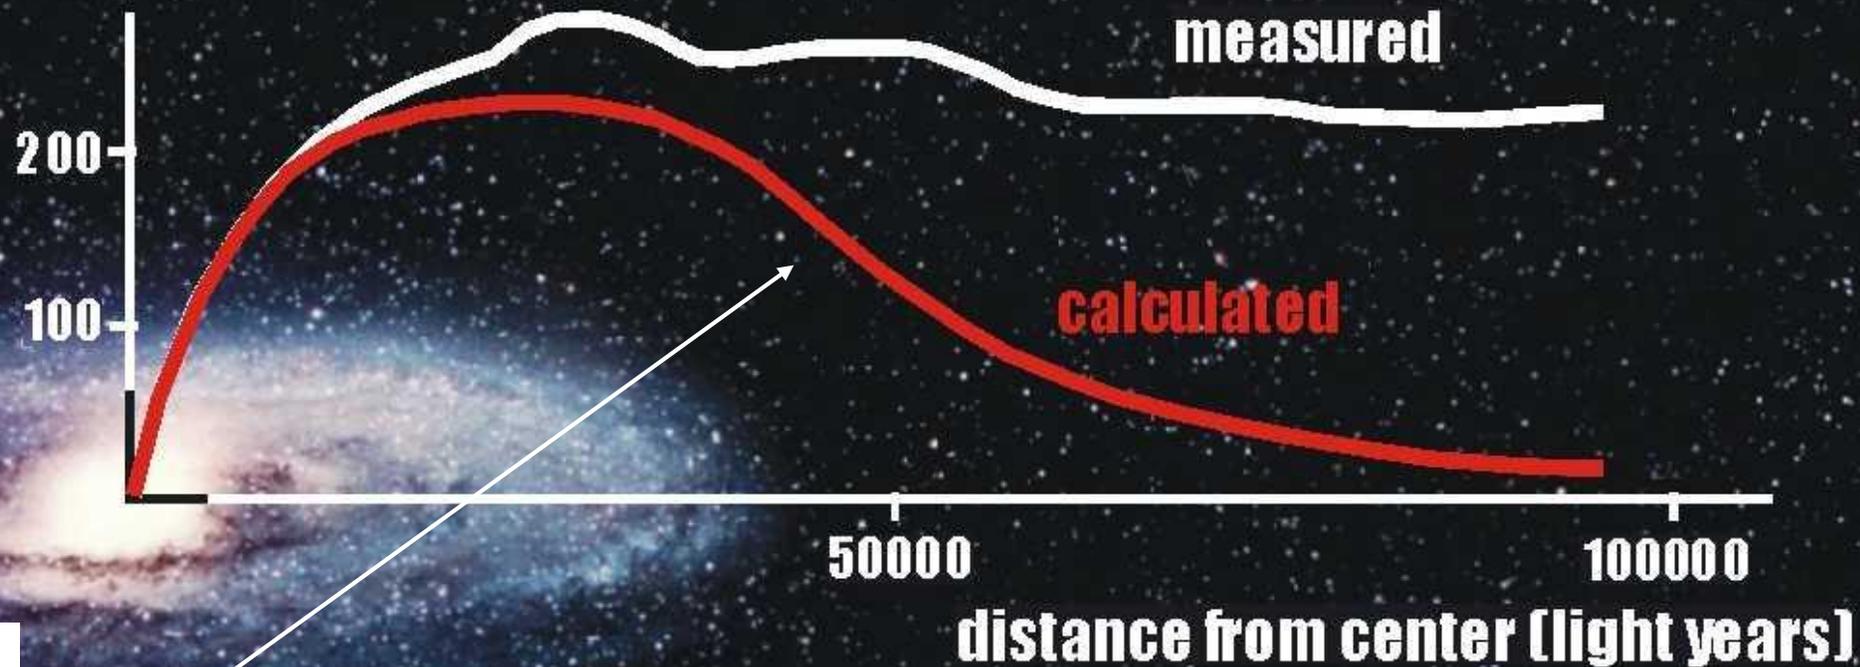

SM describes only ordinary matter, only about 5% of our Universe

How we know that most of the Universe  
is Invisible?

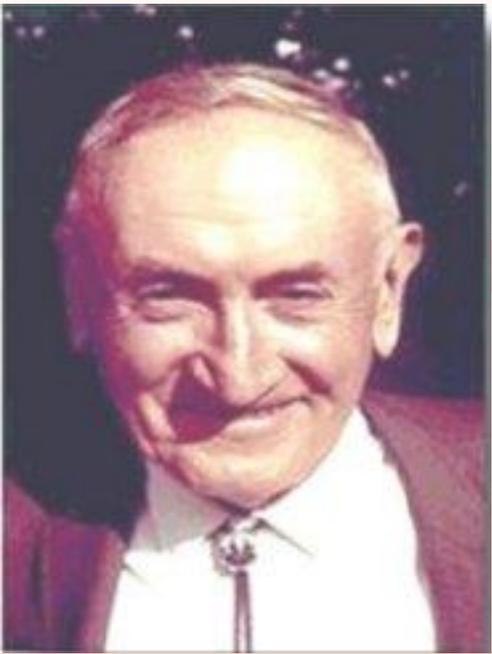

Again, Invisibles can influence observable  
matter

rotational velocity  
(km/s)

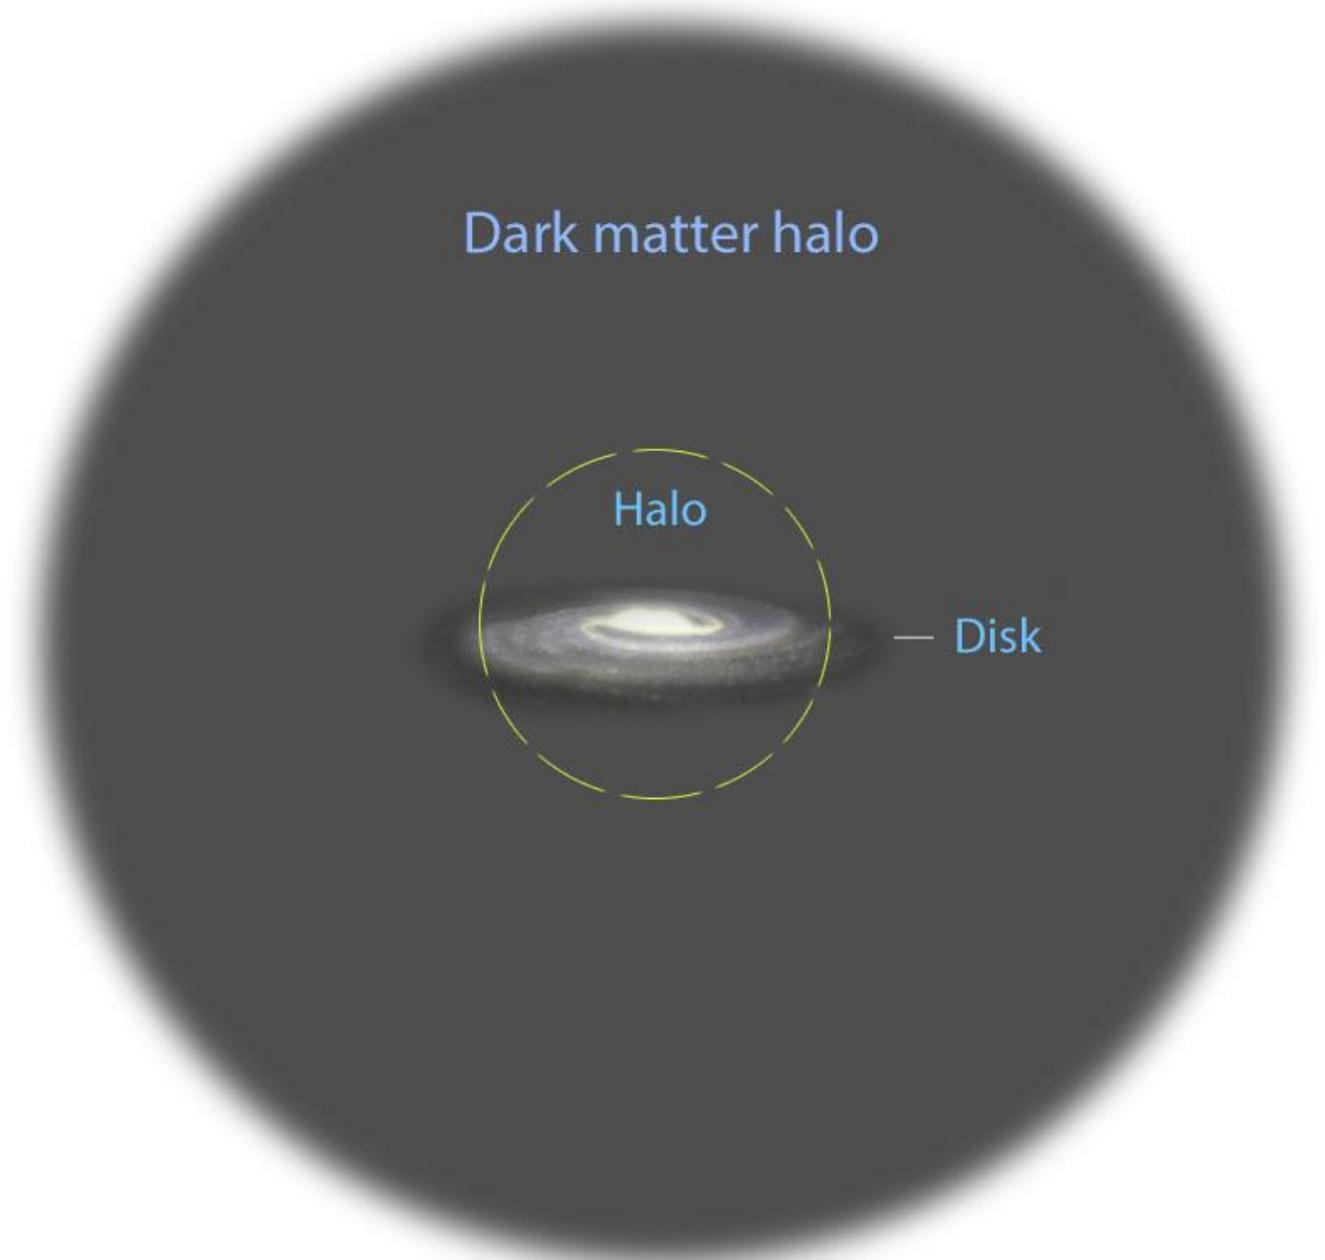

$$F = \frac{GM_{\text{Galaxy}}m}{r^2} = \frac{mv^2}{r}$$

$$v = \sqrt{\frac{GM_{\text{Galaxy}}}{r}}$$

Fritz Zwicky

Galaxies are surrounded by an invisible matter component:  
**THE DARK MATTER**

Milky Way model

A gravitational field can deviate the path of the light.

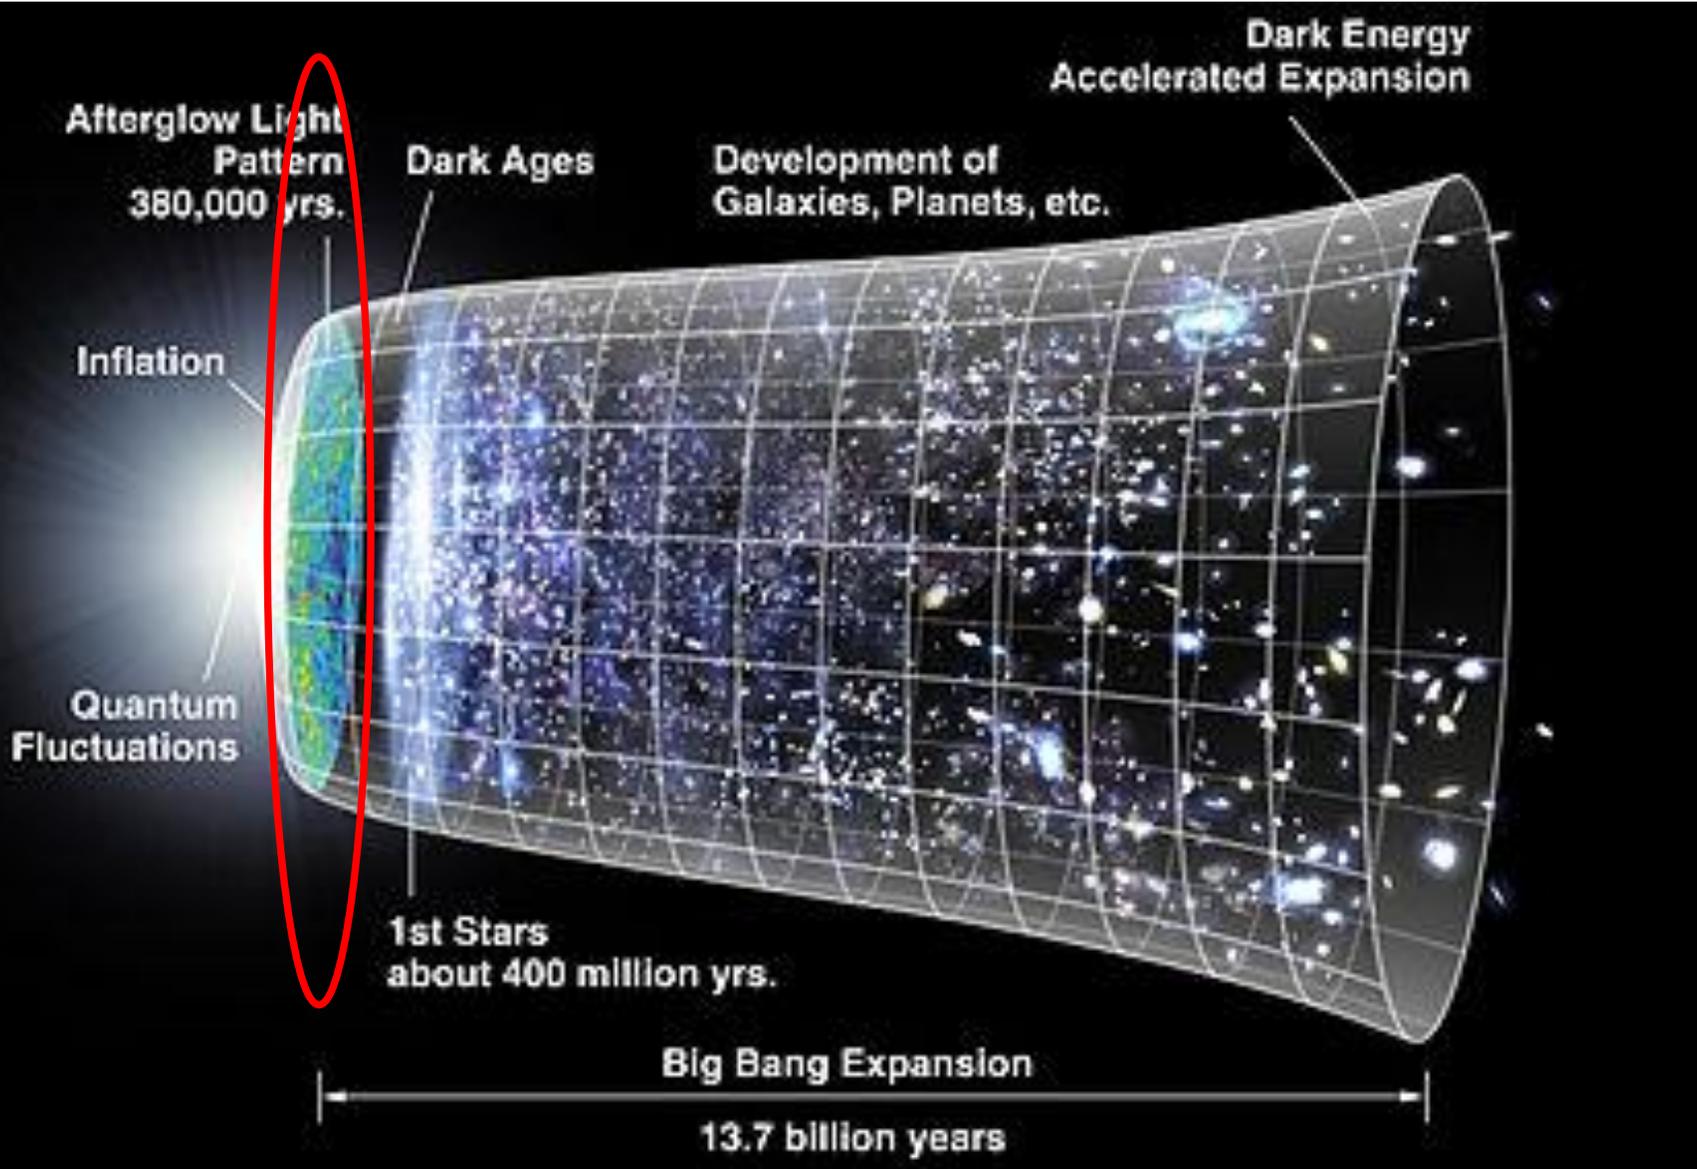

It is possible to observe invisible objects through their effect on the light of visible sources (gravitational lensing).

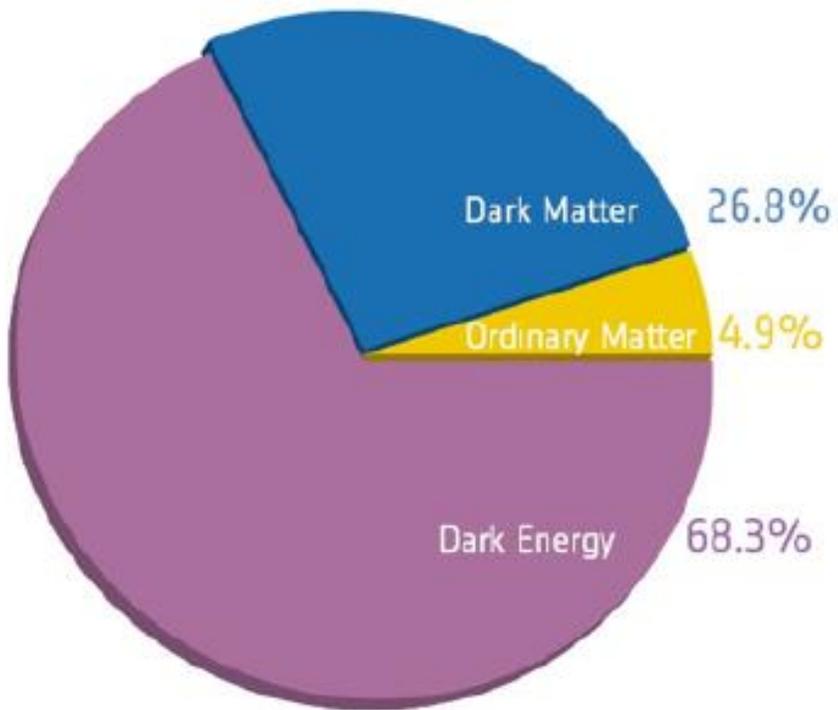

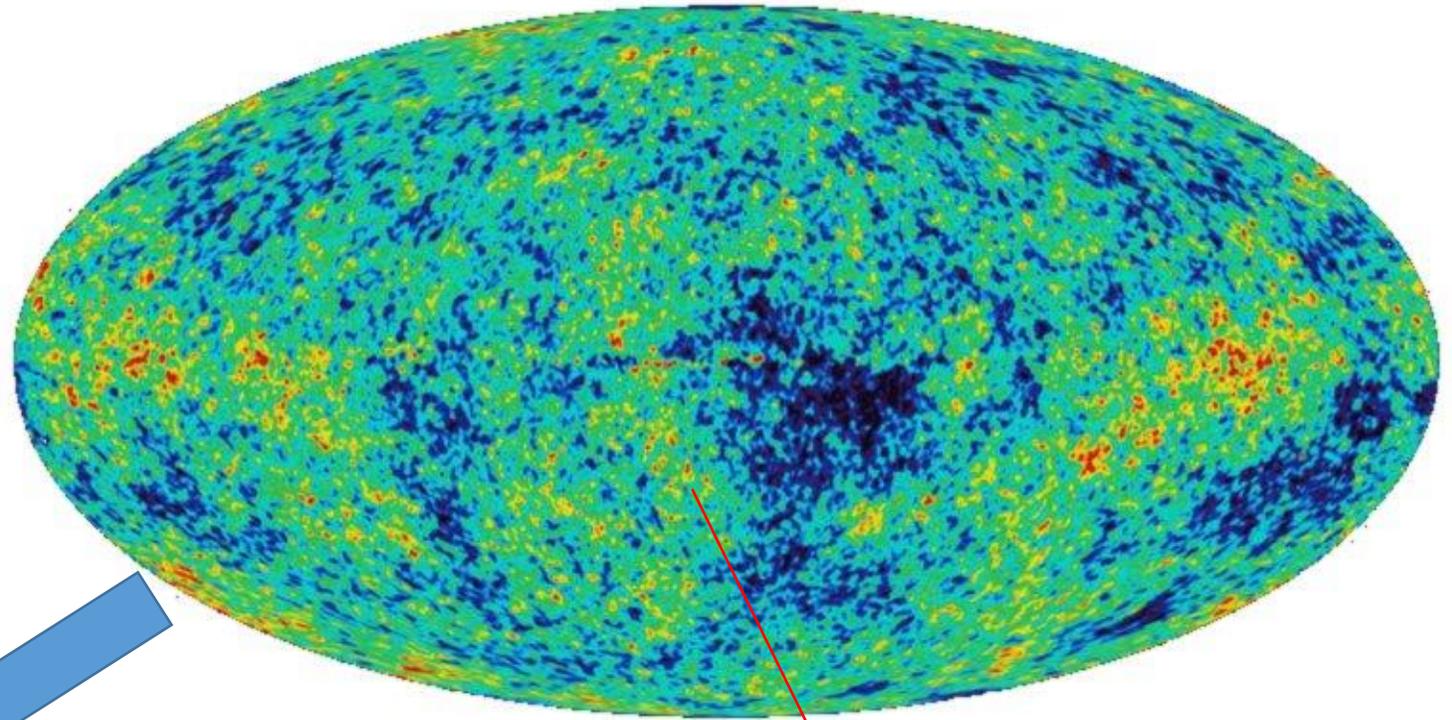

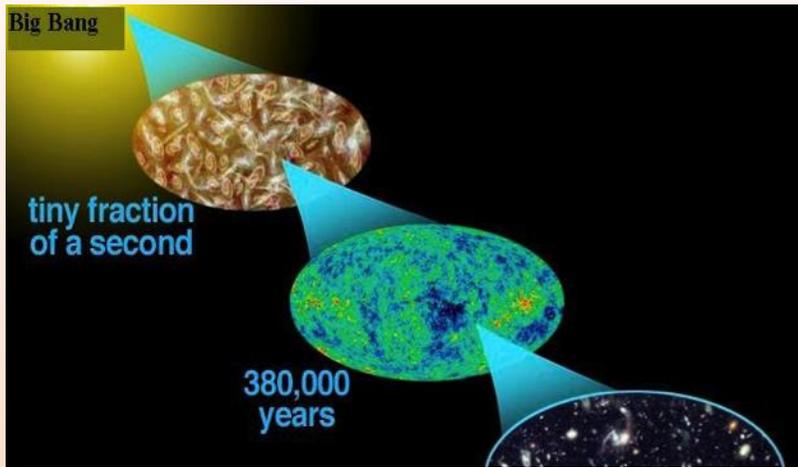

The DM halos are not perturbed by the collisions.  
The DM is "collisionless".

Dark Matter

# How we know the amount of DM in the Universe?

The DM  
influences the  
history of the  
Universe

printed in the in the

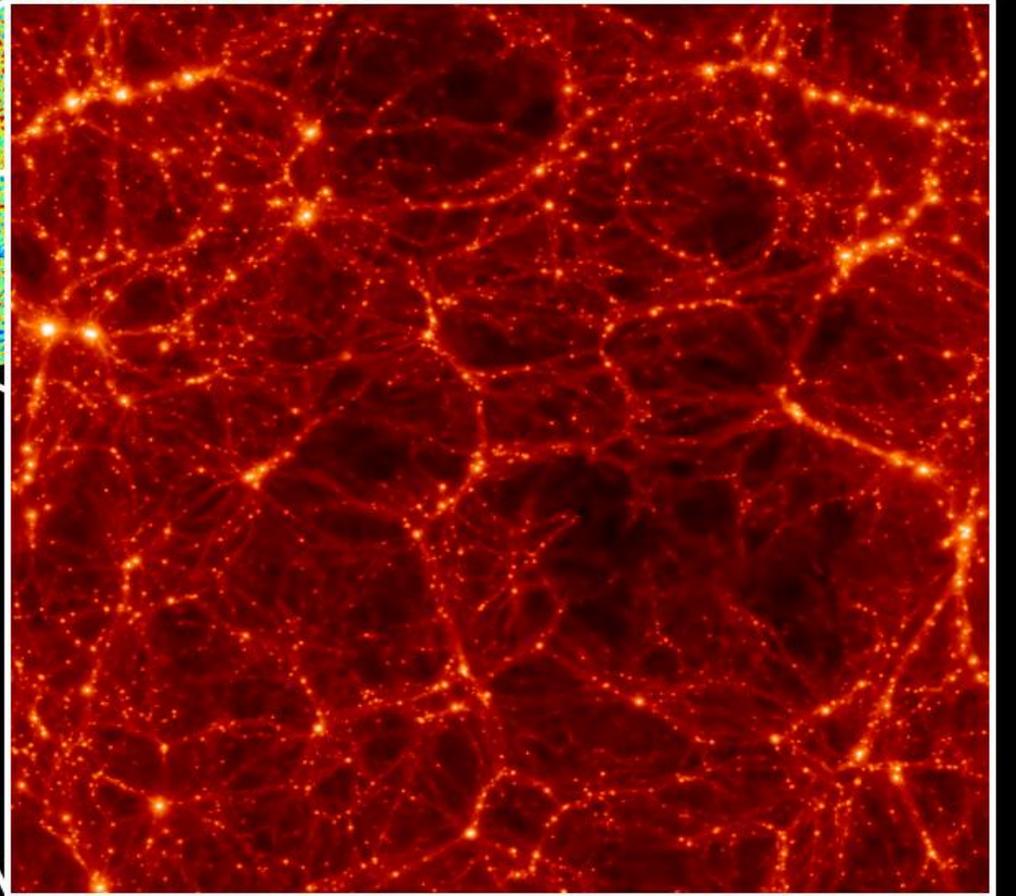

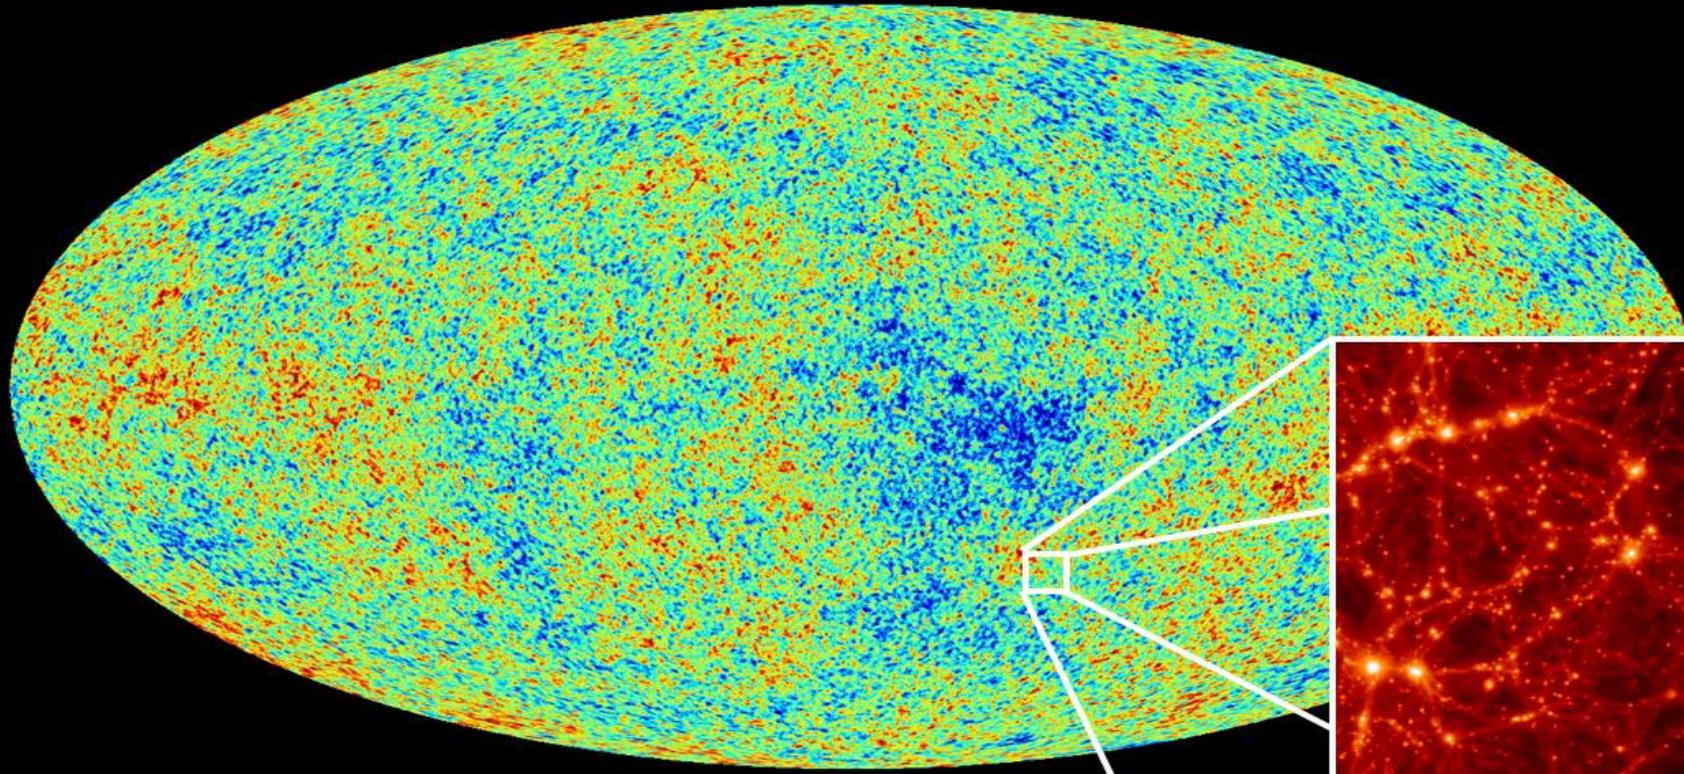

which are related to  
ated the present

The  
"Co

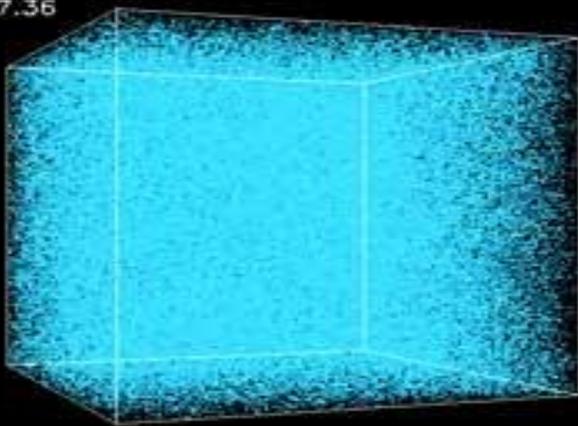

It fe  
der  
Uni

The observed CMB depends on the content of the Universe.

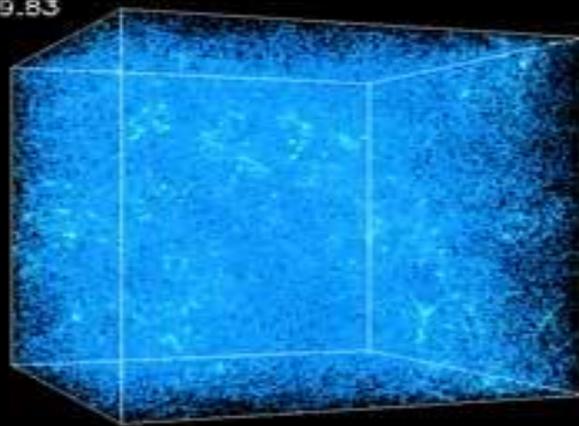

Galaxies and other structures form where there is overdensity of DM. We can infer dark matter properties by numerically simulating the evolution of structures and comparing with observations.

# What we know about dark matter from current observations?

It is not made by ordinary matter (baryon, protons, neutrons ....)

It is not dissipative, i.e. not condense in the center of galaxies (it rather form halos)

It is collisionless (bulla cluster)

Does not significantly emit, absorb or reflects light (no direct observation so far)

It consist of approximately 26% of the Universe

**We have to look for a new particle, electrically neutral, massive and stable on cosmological scales.**

In order to determine the particle nature and properties of the DM we need a direct observation.

We need to find an efficient way to compensate the tiny probability of interaction.

# Strategies for DM detection:

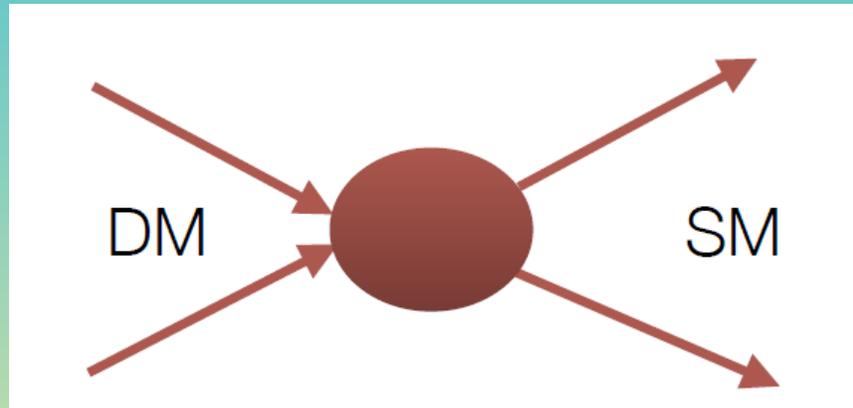

## Detection of the DM in the space

- Direct
- Indirect

## Production of the DM at collider

# Dark Matter Indirect Detection

In most of model the DM is capable of processes, dubbed annihilations, in which two DM particles are converted into two SM particles.

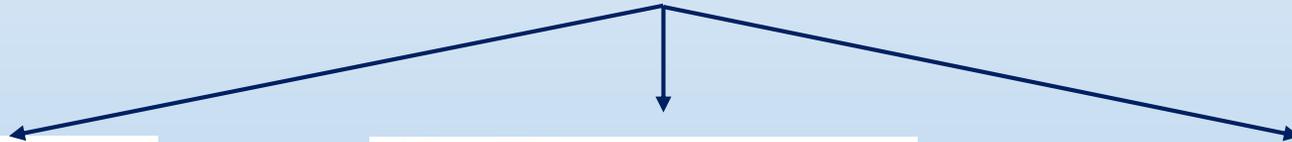

Indirect detection looks at the final products of this annihilation processes.

# Where we look for annihilation processes?

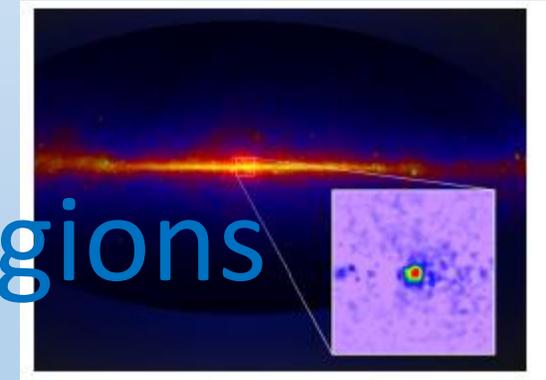

Cosmic rays

Dwarf Galaxies

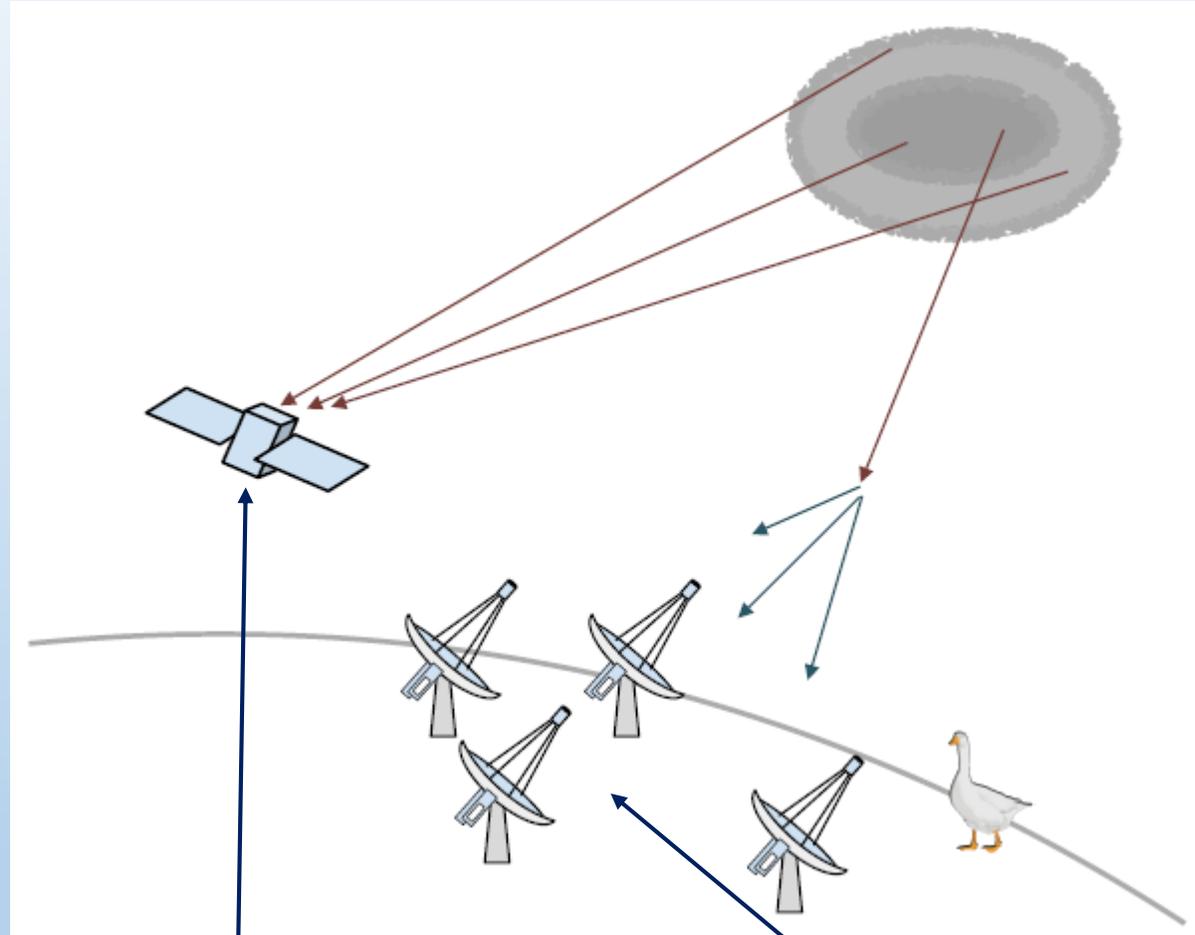

Galaxy Clusters

Galactic Center

Dark Matter Dense Regions

# How we detect Dark Matter Annihilations?

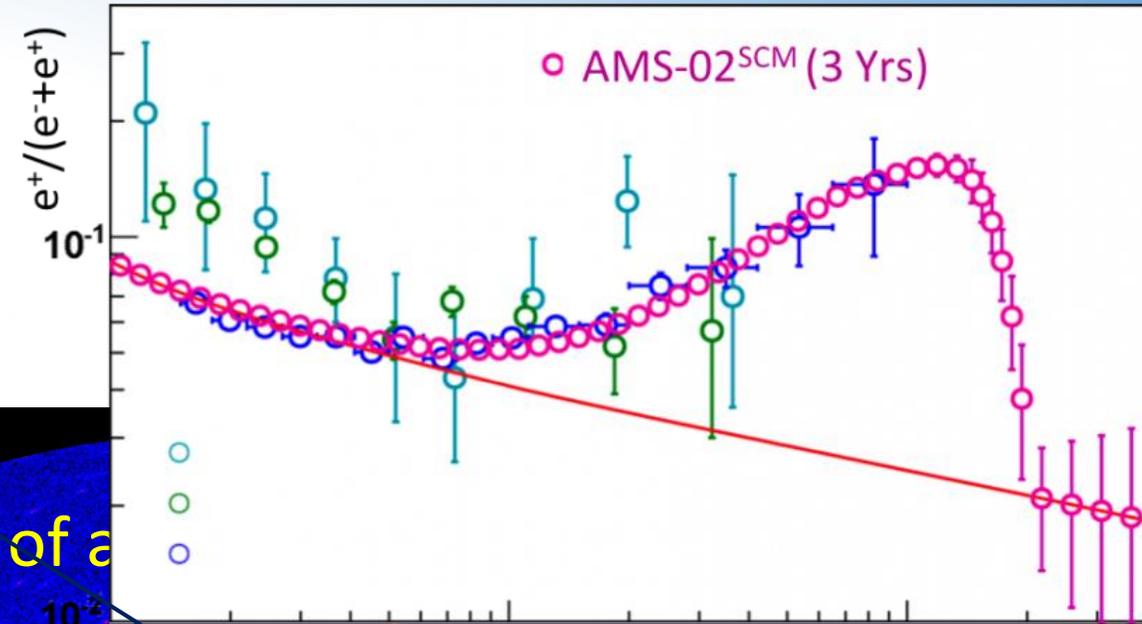

Satellites

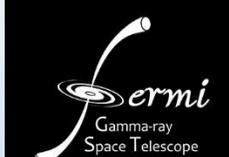

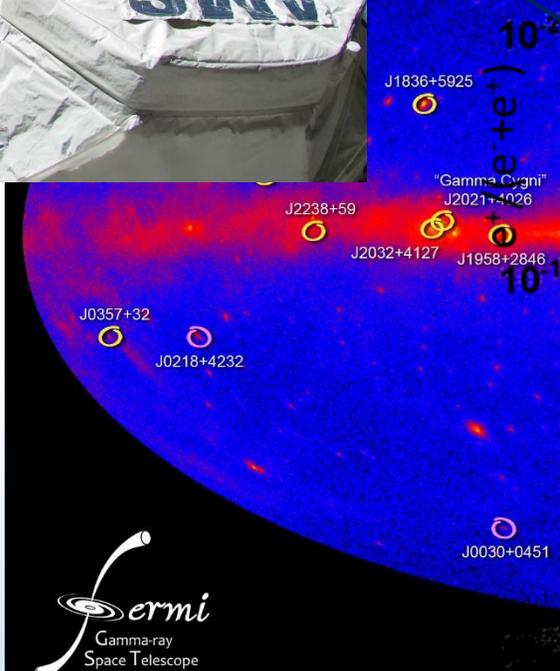

Ground Telescopes

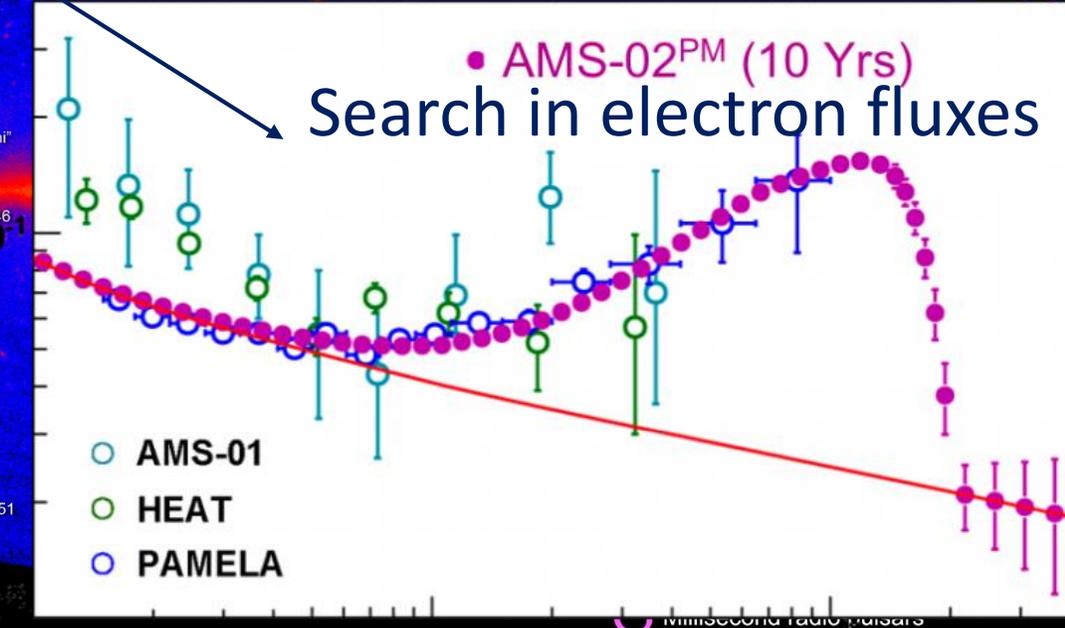

Dark Matter Candidate  $m_{\chi^0} = 200 \text{ GeV}$

Search of a

Search in electron fluxes

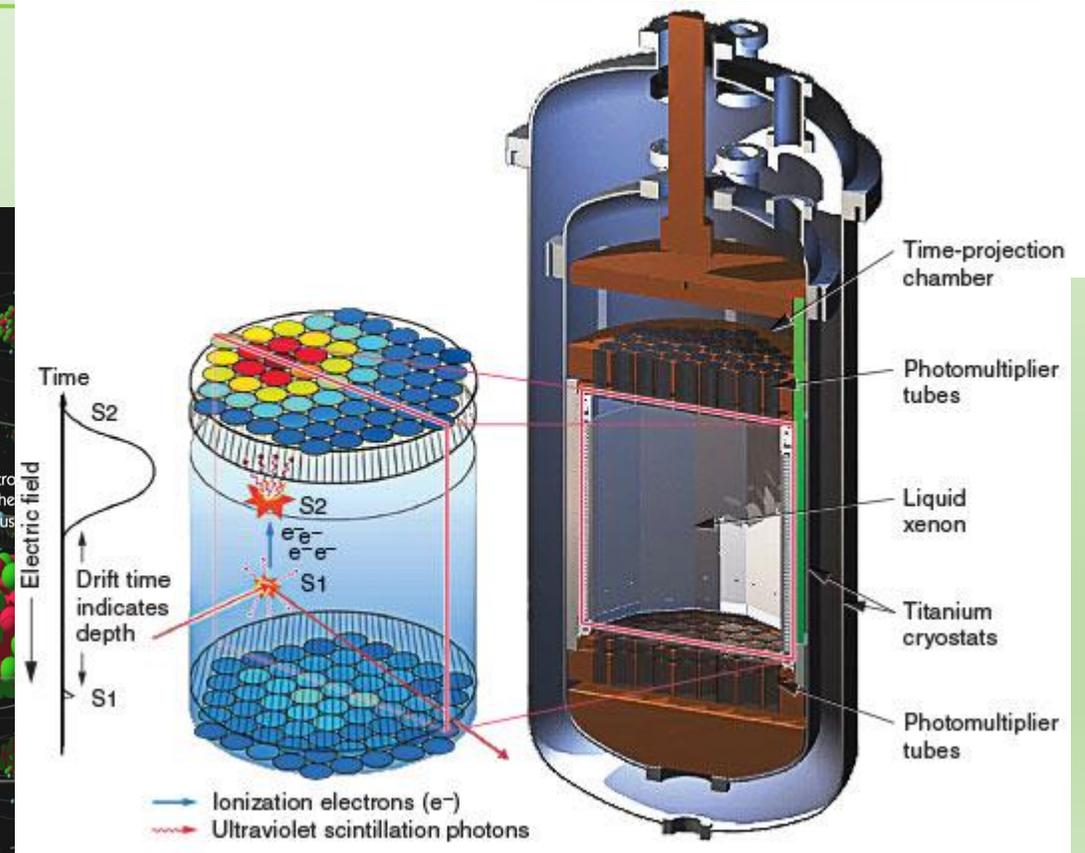

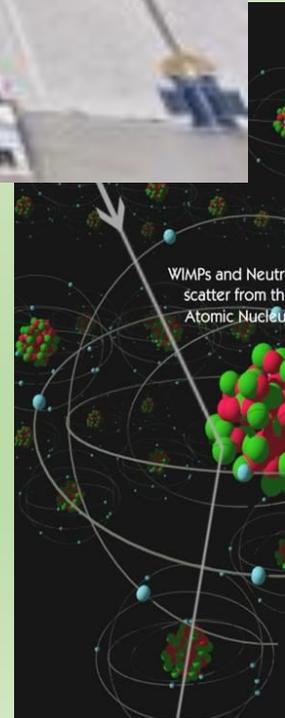

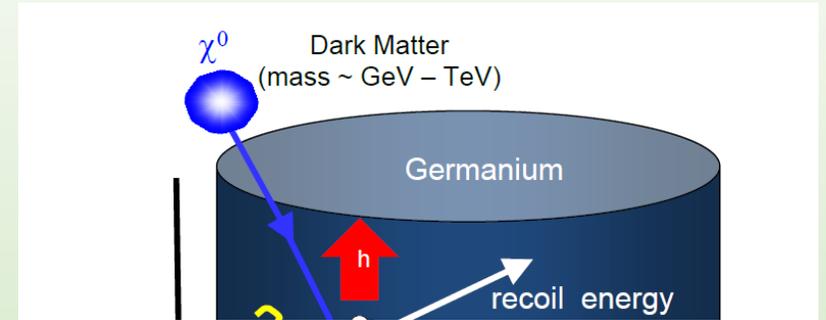

millisecond radio pulsars

# Dark Matter Direct Detection

Direct detection experiments aim to detect the DM of our galactic halo which hit the nuclei of a detector. Big volumes and long exposure times are needed.

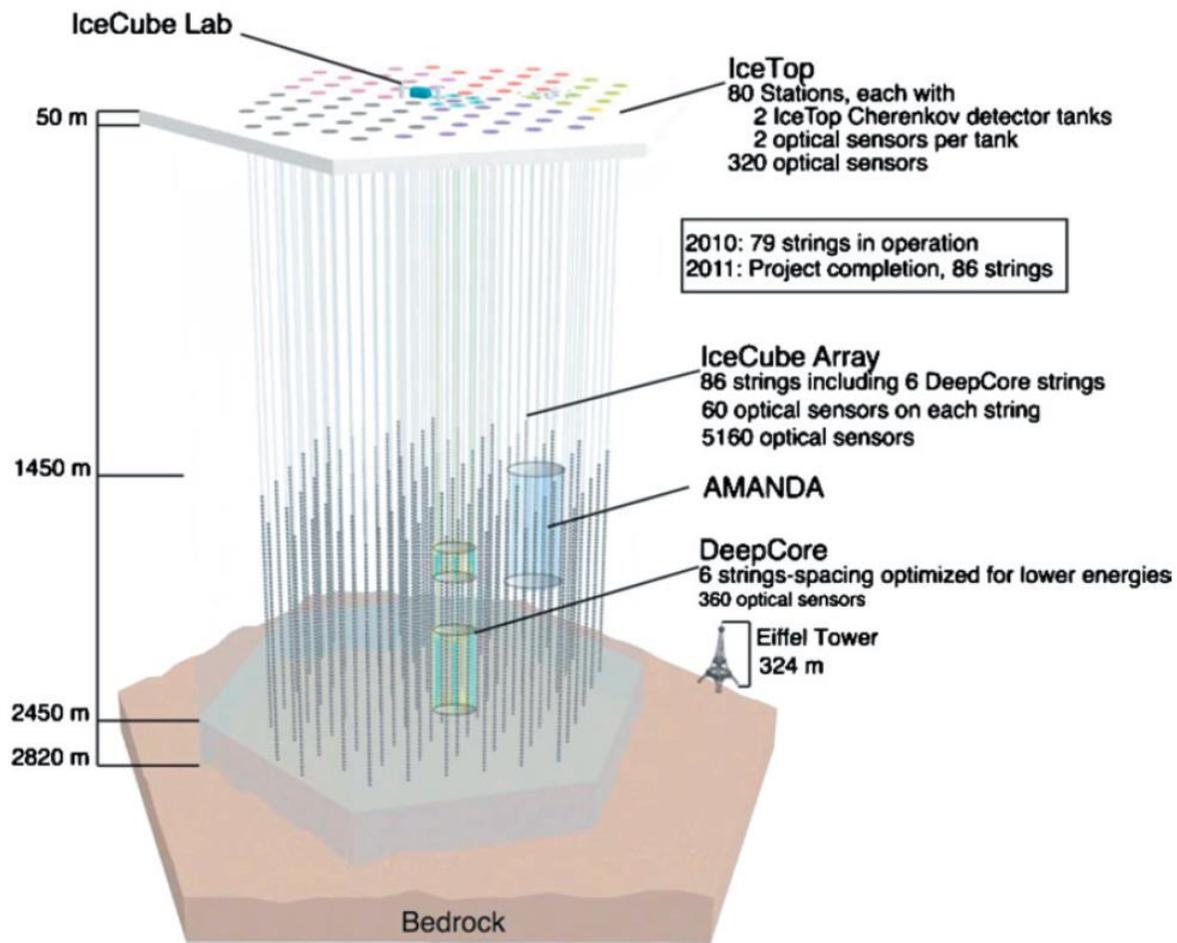

Ionization electrons ( $e^-$ )  
Ultraviolet scintillation photons

# Many detectors all over the world...

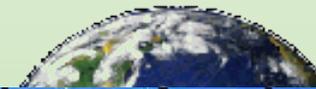

Picture from L. Baudis, 2012

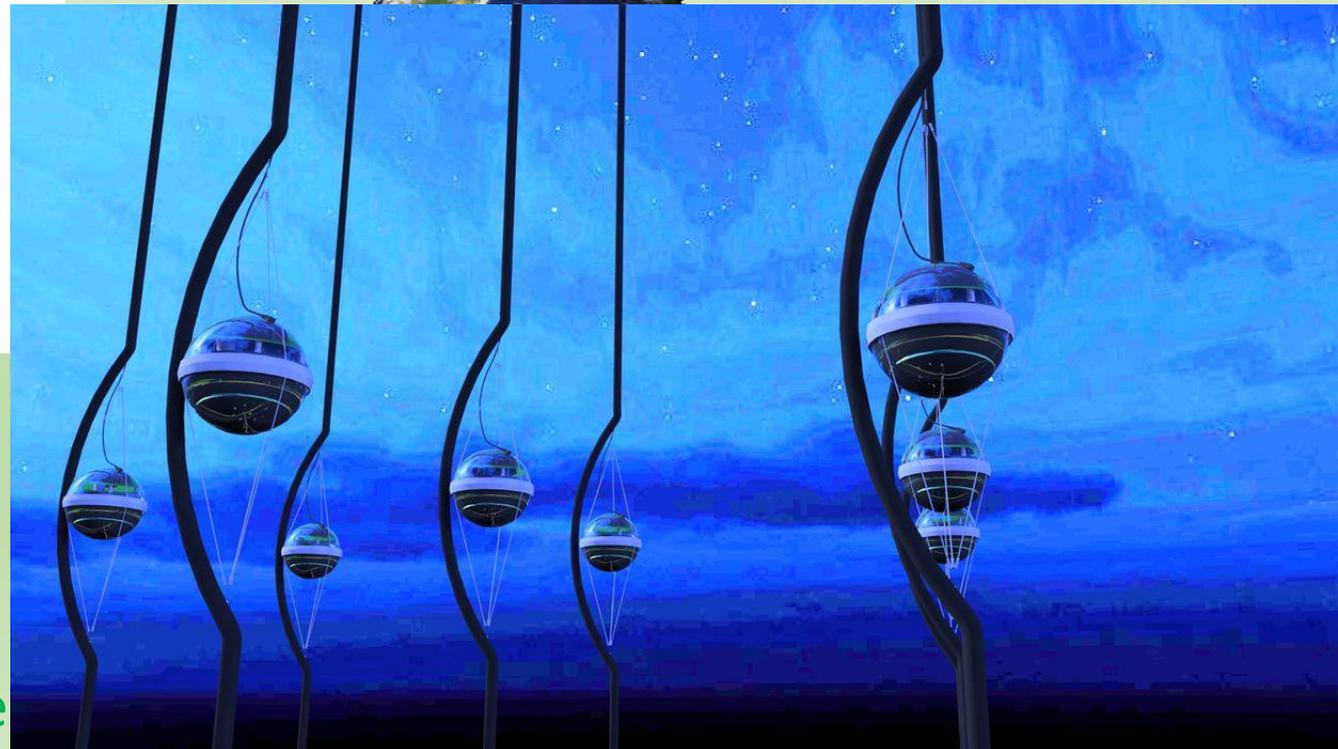

← convection

just outside

Earth

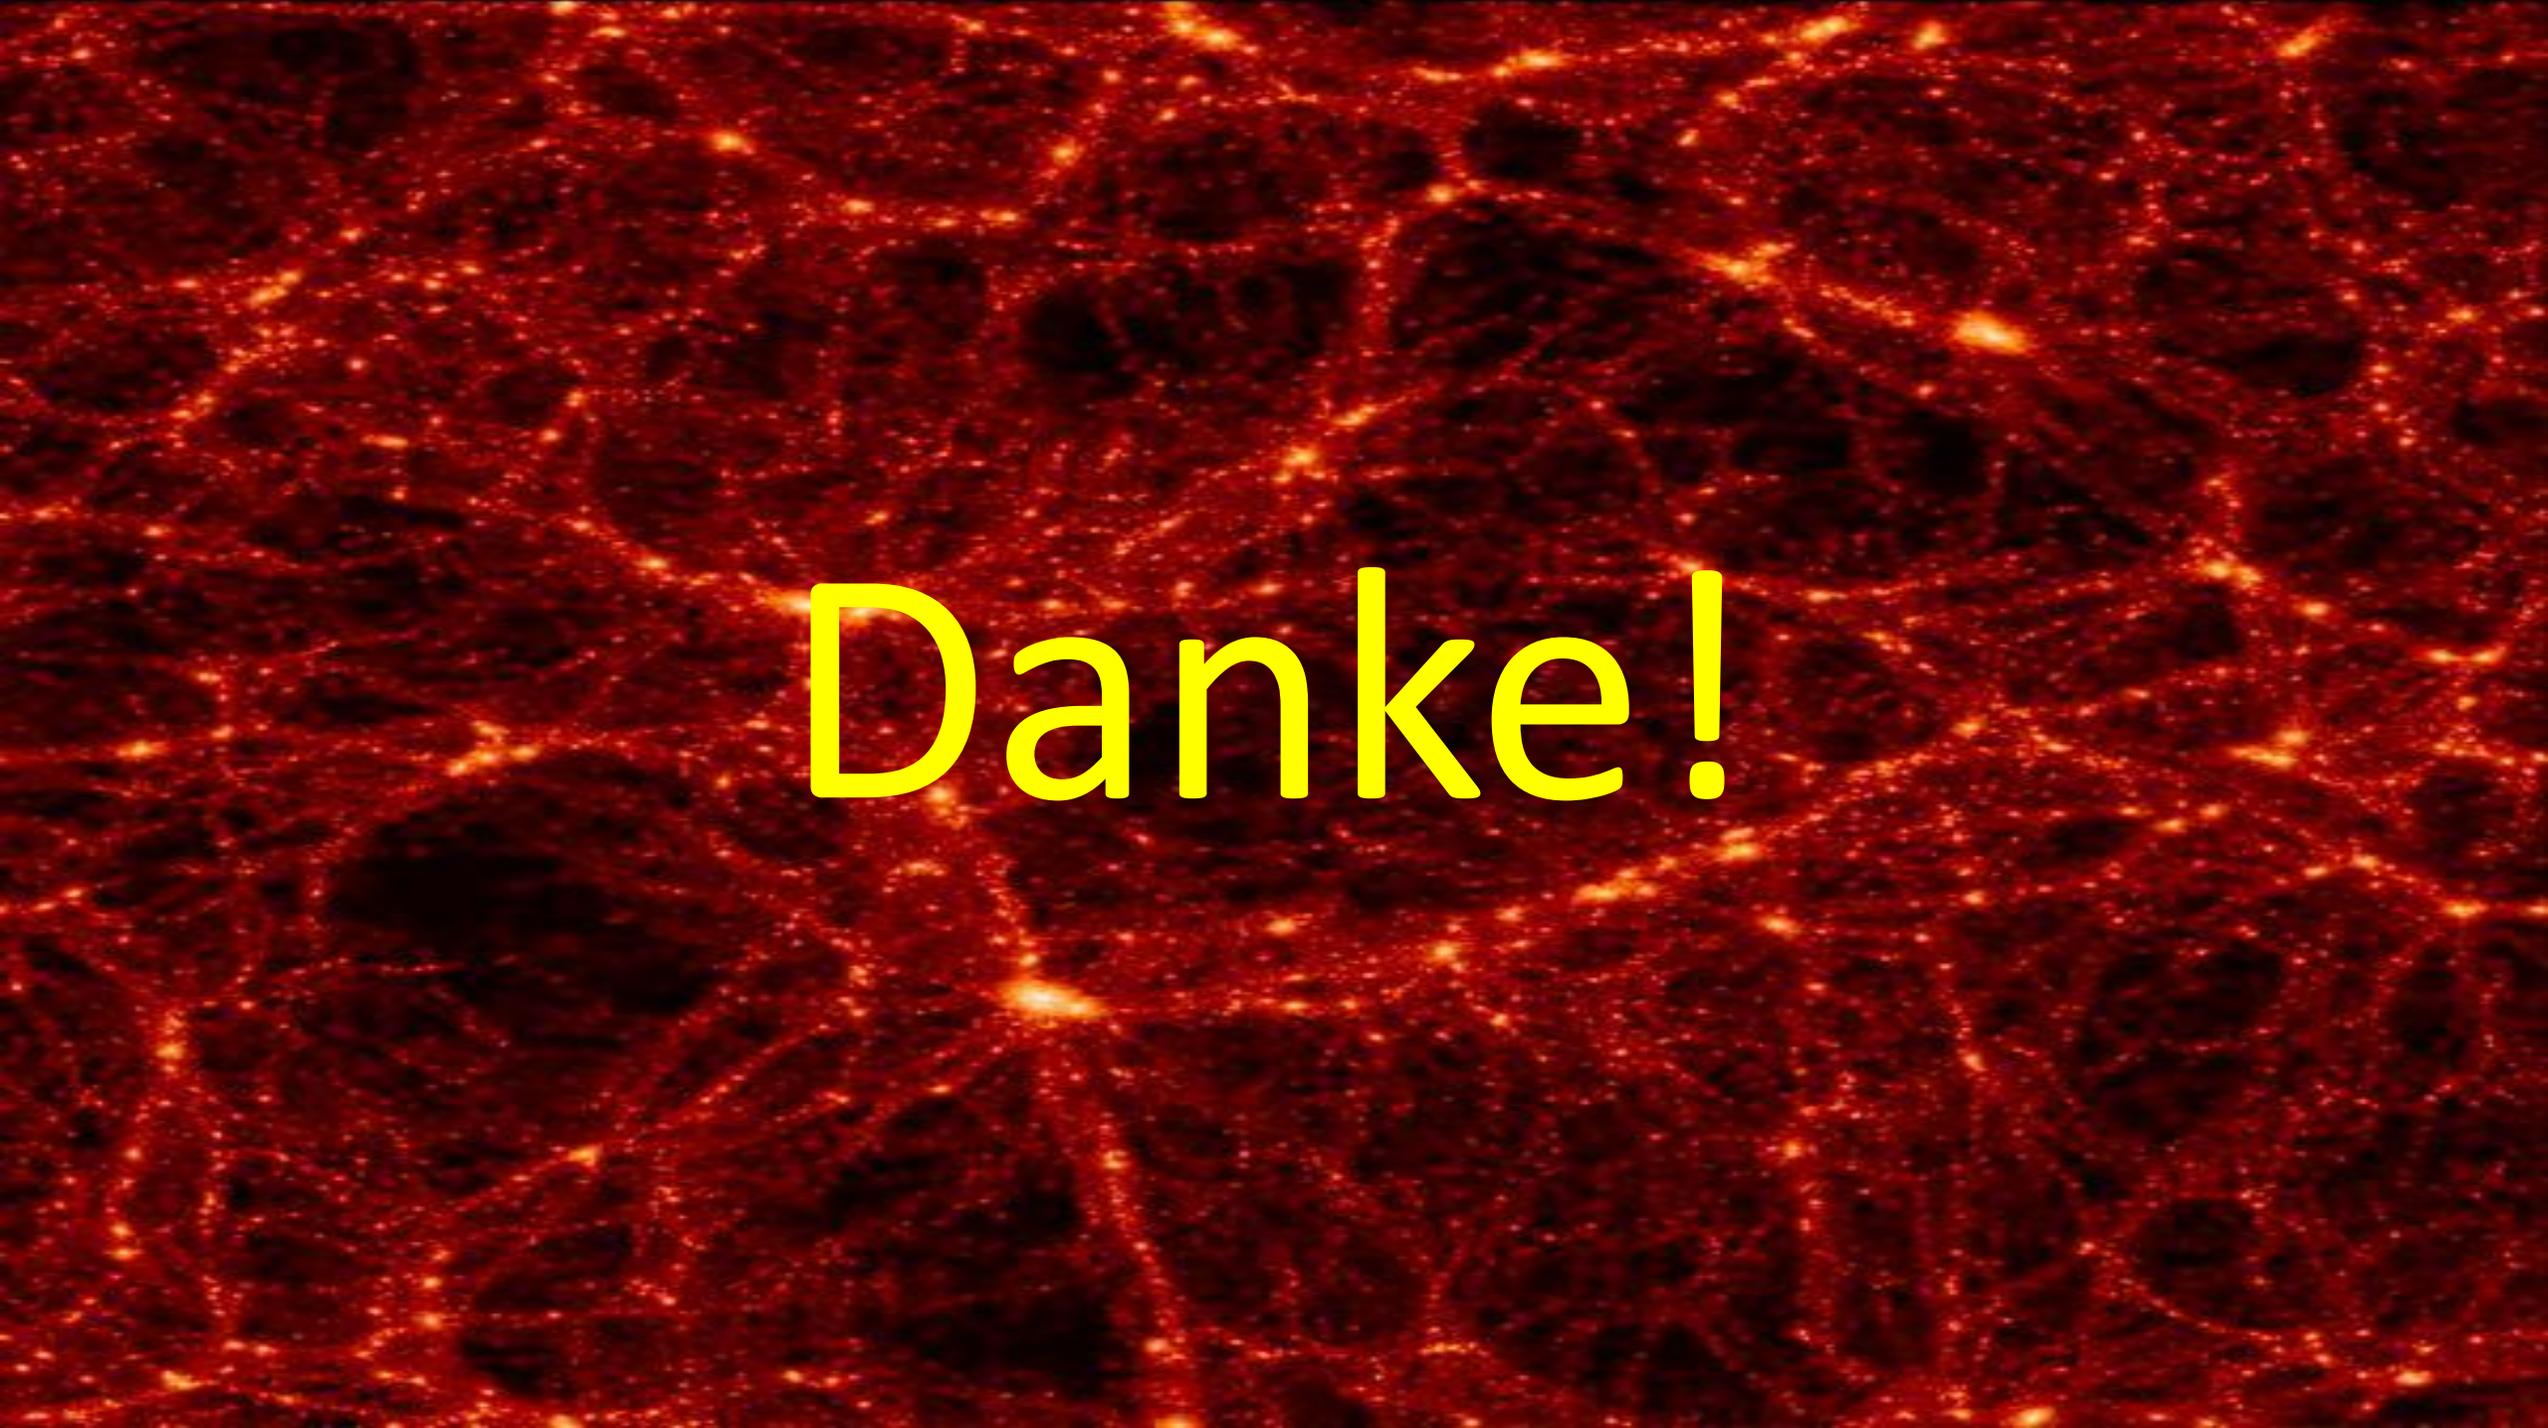

The sun can capture with its gravitational field in its overdense inner shells.  
We can detect neutrinos produced by possible

Our Universe is deeply influenced by “Invisible” components.

Revealing their nature and properties is one of the most intriguing challenges of Science today

Research is very active and progresses are expected rather soon

Danke!
